

Project 1: REST API FUNDAMENTALS

Summary:

This project is a simple flashcards web application created to understand the fundamentals of REST API.

- **The Backend (Server):** Built using Python and FastAPI. It waits for requests from the browser, manages the flashcards, and serves data.
- **The Frontend (Interface):** Built using React and Vite, it provides a clean, light-colored visual screen where users can see flashcards, click to flip them to reveal answers, and type into a form to create new ones.

Requirement Checklist:

Key Requirements		
Local Server Setup	The app uses Python (FastAPI) paired with a tool called Uvicorn to run a server locally on your computer.	In backend/main.py where <code>app = FastAPI()</code> is created. When run, it listens for requests at <code>http://127.0.0.1:8000</code> .
GET Route	The path used to read and fetch flashcards.	<code>@app.get("/api/cards")</code> HTTP GET
POST Route	The path used to send and add a new flashcard.	<code>@app.post("/api/cards")</code> HTTP POST
Structured JSON	server packages flashcards inside clean text blocks with clear labels (key-value pairs).	When the frontend communicates with the backend, it reads data using <code>response.json()</code>
